Erroneously in Fig. 3 the isolines of significant wave height were reported to be plotted every 1 mm while they are every 1 m. Here below is the correct figure caption:

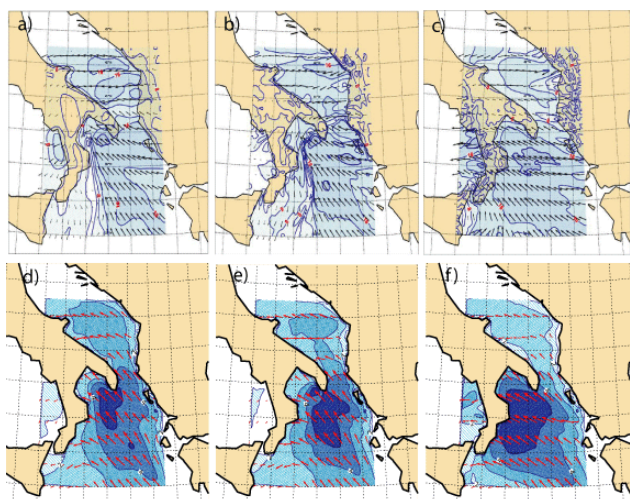

Fig. 3. Wind (top panels) and wave (bottom panels) fields at 12:00 UTC, 11 December 2005, corresponding to the peak of the storm: (a) BOLAM, (b) MOLOCH, (c) WRF forecast wind. Isotachs are plotted every 4 m s^{-1} , the stronger is the wind the deeper is the blue tone. Wave heights forecast by WAM using (d) BOLAM, (e) MOLOCH and (f) WRF wind field as input. Isolines of significant wave height are plotted every 1 m. Blue tones for higher waves, the higher are the waves the darker is the color. Red arrows indicate the mean flow direction of waves.

Erroneously in Sect. 4 – Results, the sentence “ Because the wave fields are an integrated effect of the wind over the sea, the attention is mainly focused ...” must be read as “Because the aim of the project is mainly concentrated over regional areas, the attention is mainly focused ...”.

In Sect. 4.4 – Comparison with measurements, after mentioning the references to “(Cavaleri et al., 2003, 2006)” add also the study by Ardhuin et al., 2007.
